Field of the Invention This invention relates to a motion-detecting device using a two-dimensional type solid-state image sensor comprising a plurality of photoelectric transducer elements arranged in a two-dimensional matrix form. More particularly, the invention relates to such a solid-state image sensor arranged in the form of a matrix and having a light-shielding function for preventing light from a light source from reaching the peripheral portions of the solid-state image sensor. 2. Related Background Art In general, a two-dimensional type solid-state image sensor is arranged in the form of a matrix. The device is used for reading an image formed on a film. In particular, in a color image reading device, a multiplicity of light-receiving elements such as CCDs for reading a color image are arranged in a two-dimensional matrix, and read image signals for respective colors. The image signal read by each light-receiving element is output as a video signal. For example, in the camera, the light incident upon the solid-state image sensor enters the camera to form an image, and the image is guided to a focus optical system and an image-receiving system, to be brought into focus. At this time, an object image and its periphery (i.e., a light-shielding area) are automatically light-shielded. However, as the light-shielding area is widened, it is occasionally necessary to shield the light-shielding area to limit light from, for example, 1cdb3666d
